ABSTRACT: Lymphedema is a condition in which the lymph hearts fail to pump fluid from the lymph sacs of anurans and other amphibians. This causes the sacs to fill with fluid and provide the frog with balloon-like swellings or overall appearance. The condition has previously been connected with various diseases including tadpole edema virus and chytrids. We observed lymphedema in six anuran species: Blanchard's Cricket Frog (Acris blanchardi)*, Fowler's Toad (Anaxyrus fowleri)*, Squirrel Treefrog (Hyla squirella)*, Illinois Chorus Frog (Pseudacris illinoensis)*, Wood Frog (Rana sylvatica), and the Southern Leopard Frog (Rana sphenocephala)* (species with * are species records for lymphedema).

Key Words: lymphedema, Batrachochytrium dendrobatidis, Flavobacterium indologenes, chytrids, inflammation.

INTRODUCTION

Reports of lymphedema-like disorders in anurans are rare in the literature. This disorder, first described in 1915 (Moore, 1915) has been identified as one of the most common abnormalities in captive bred Xenopus (clawed frogs). This lymphatic dysfunction most commonly results before or just after metamorphosis. It is characterized by extreme inflammation of tissues giving the frog a ballooned appearance. Apparently, the lymph hearts fail to drain the lymph sacs and do not reach maturity. Wild-caught lymphedematous Rana catesbeiana tadpoles have been reported with lymphedema of only the femoral and crural lymph sacs (Hintz, 1963). A similar condition was also reported in overwintering tadpoles and adults of Mountain Yellow-legged Frogs (Rana muscosa) (Bradford, 1984).

Iridoviruses known from amphibians are classified as polyhedral cytoplasmic amphibian viruses (PCAV). One of these groups, tadpole edema virus (TEV), mimics subcutaneous hydrops. This virus is transmitted in the water and causes mortality in newly metamorphosed frogs. Its symptoms include subcutaneous edema, petechial hemorrhages, and necrosis in the liver, kidneys, gastrointestinal tract, and skeletal muscle (Faeh et al., 1998). Wolf et al. (1968) performed histopathologic analyses of edematous American Bullfrog tadpoles identifying a causal agent, the tadpole edema virus (TEV). They later isolated TEV from apparently healthy American Bullfrogs, though it could not be isolated from either Anaxyrus or Scaphiopus species from the original source pond. TEV was isolated from American Bullfrog tadpoles from Wisconsin, Alabama, West Virginia, North Carolina, and along the Mississippi River in Arkansas (Wolf et al., 1969). However, edema has also been attributed to the bacterium Flavobacterium indologenes (Ol-
son et al., 1992) and the fungus \textit{Batrachochytrium dendrobatidis} (Martel et al., 2011).

American Bullfrog tadpoles appear to be very sensitive to TEV (Wolf et al., 1969), but little is known about susceptibility of \textit{Acris} species to this pathogen. Wolf et al. (1969) found that if the virus was added to water containing 18 one-day-old American Bullfrog tadpoles, that death ensued beginning after 5 days of exposure. Mortality peaked at 53% by the 7th day of this study. Forty-nine-day-old tadpoles showed first signs of mortality on the 5th day after exposure, with mortality peaking at 37% on the 9th day. All tadpoles were dead by the 13th day. Clear-cut histopathology included necrosis of the liver, kidneys, and digestive tract. Liver necrosis was identified by the second day after exposure. Kidney necrosis and edema were expressed after the 4th day. By the 5th day the digestive tract started to show necrosis.

Because lymphedema is closely associated with TEV it is important to document and report its occurrence in regions where this condition has not previously been reported.

MATERIALS AND METHODS

Observations of lymphedema in Anurans were recorded as encountered from 1997 - 2020. Most specimens were released, but others were anesthetized with dilute chloretone, fixed in 10% formalin, preserved in 70% ethanol and deposited in the Arkansas State University Museum of Zoology herpetological collection (ASUMZ), Illinois Natural History Survey collection (INHS), or the Louisiana State University at Shreveport Museum of Life Sciences (LSUSMF).

RESULTS AND DISCUSSION

Incidence of lymphedema among wild-caught anurans was relatively low (Table 1), but was observed in 4 of 5 species in this study. Wood Frogs (\textit{Rana sylvatica}) are a charismatic species of frog common in much of North America. They breed in explosive choruses over a few nights in late winter to early spring. The incidence in Wood Frogs was associated with a die-off of frogs during the breeding chorus in the Sylamore District of the Ozark National Forest in Arkansas (Trauth et al., 2000). In Wood Frogs, lymphedema ranged from the entire torso to localized single lymph sacs on the legs or patches on the back (Fig. 1).

The Illinois Chorus Frog (\textit{P. illinoensis}) and Strecker’s Chorus Frog (\textit{Pseudacris streckeri}) are small fossorial frogs that occur in Arkansas and Oklahoma. The range of Illinois Chorus Frogs in Arkansas has severely contracted, most likely due to precision leveling of the farmland in which they reside (McCallum and Trauth, 2002; Trauth et al., 2006). We observed a single Arkansas frog with lymphedema of the right dorsal lymph sac (Fig. 1). This individual appeared normal in movements and activity although it did not appear to be calling or acting as a satellite to other calling males (McCallum et al., 2003). Illinois Chorus Frogs were also observed with frostbite scars (n = 10), red inguinal pustules (n = 2), a dysfunctional vocal sac (n = 1), and a missing forelimb (n = 1), (McCallum et al., 2006; McCallum et al., 2001b). No Strecker’s Chorus Frogs from Oklahoma were observed with lymphedema.

Illinois Chorus Frog (\textit{Pseudacris illinoensis}). C. Squirrel Tree Frog (\textit{Hyla squirella}). D. Blanchard’s Cricket Frog (\textit{Acris blanchardi}).
The Southern Leopard Frog (Rana sphenocephala) is a generic frog species easily confused with several other species of leopard frogs with whose ranges they overlap. They are common to creeks, grasslands, forests, and ponds throughout the southeastern United States. Among 66 post-metamorphic Southern Leopard Frogs that were examined, a few (est. 3-4) were observed with lymphedema. However, the exact numbers were not recorded among malformed frogs in that study (McCallum, 1997), nor were possible incidences of partial lymphedema noticed.

Fowler’s Toad (Anaxyrus fowleri) is an average sized toad occurring across the eastern half of the United States. A single metamorph had lymphedema. It seemed otherwise normal, except that it had difficulty moving with the disorder. No Spring Peepers (Pseudacris crucifer) or Gray Treefrogs (Hyla versicolor or H. chrysoscelis) were observed with the condition despite occurring in locations where other species had it (Wood Frogs, Southern Leopard Frogs, Blanchard’s Cricket Frogs).

The Squirrel Treefrog (Hyla squirella) is a common arboreal frog of the Southeastern United States, although it was unknown to the Shreveport, Louisiana area at the time of this observation. We collected five near-metamorphosed tadpoles at Loggy Bayou Wildlife Management (Bowie Co., Louisiana, USA) and placed them in a 20 L aquarium containing water from the collection site. They appeared morphologically normal. Upon metamor-
